Apple iOS 4 Security Evaluation

Dino A. Dai Zovi
Trail of Bits LLC

Disclaimers

- I have never worked for Apple, but I have a crippling addiction to buying and tinkering with their products.
- I have never received any monetary compensation from Apple, but they have sent me some free shwag
- I have been mistaken by strangers on the street for being an off-duty Apple Store employee
- I hacked a Mac once, but don’t worry, it wasn’t yours.
- Charlie Miller and I wrote an entire book on hacking the Mac and I still have never met Steve Jobs. I blame Charlie.

Acknowledgements

- iPhone jailbreak developer community
  - Chronic Dev Team, Comex for releasing tools with source
  - The iPhone Wiki for excellent up-to-date documentation
- Other security researchers with great iOS research
  - Jean-Baptiste Bedrune, Jean Sigwald (SOGETI ESEC)
  - Dion Blazakis
  - Stefan Esser

Focus of This Talk

- What enterprise users need to know about iOS security features and properties to make informed deployment, configuration, usage, and procedure decisions
  - How iOS security compares to competing mobile platforms
- Assorted iOS implementation details and internals
- Interesting places for reverse engineers and vulnerability researchers to look (if they are paying close attention)

Overview

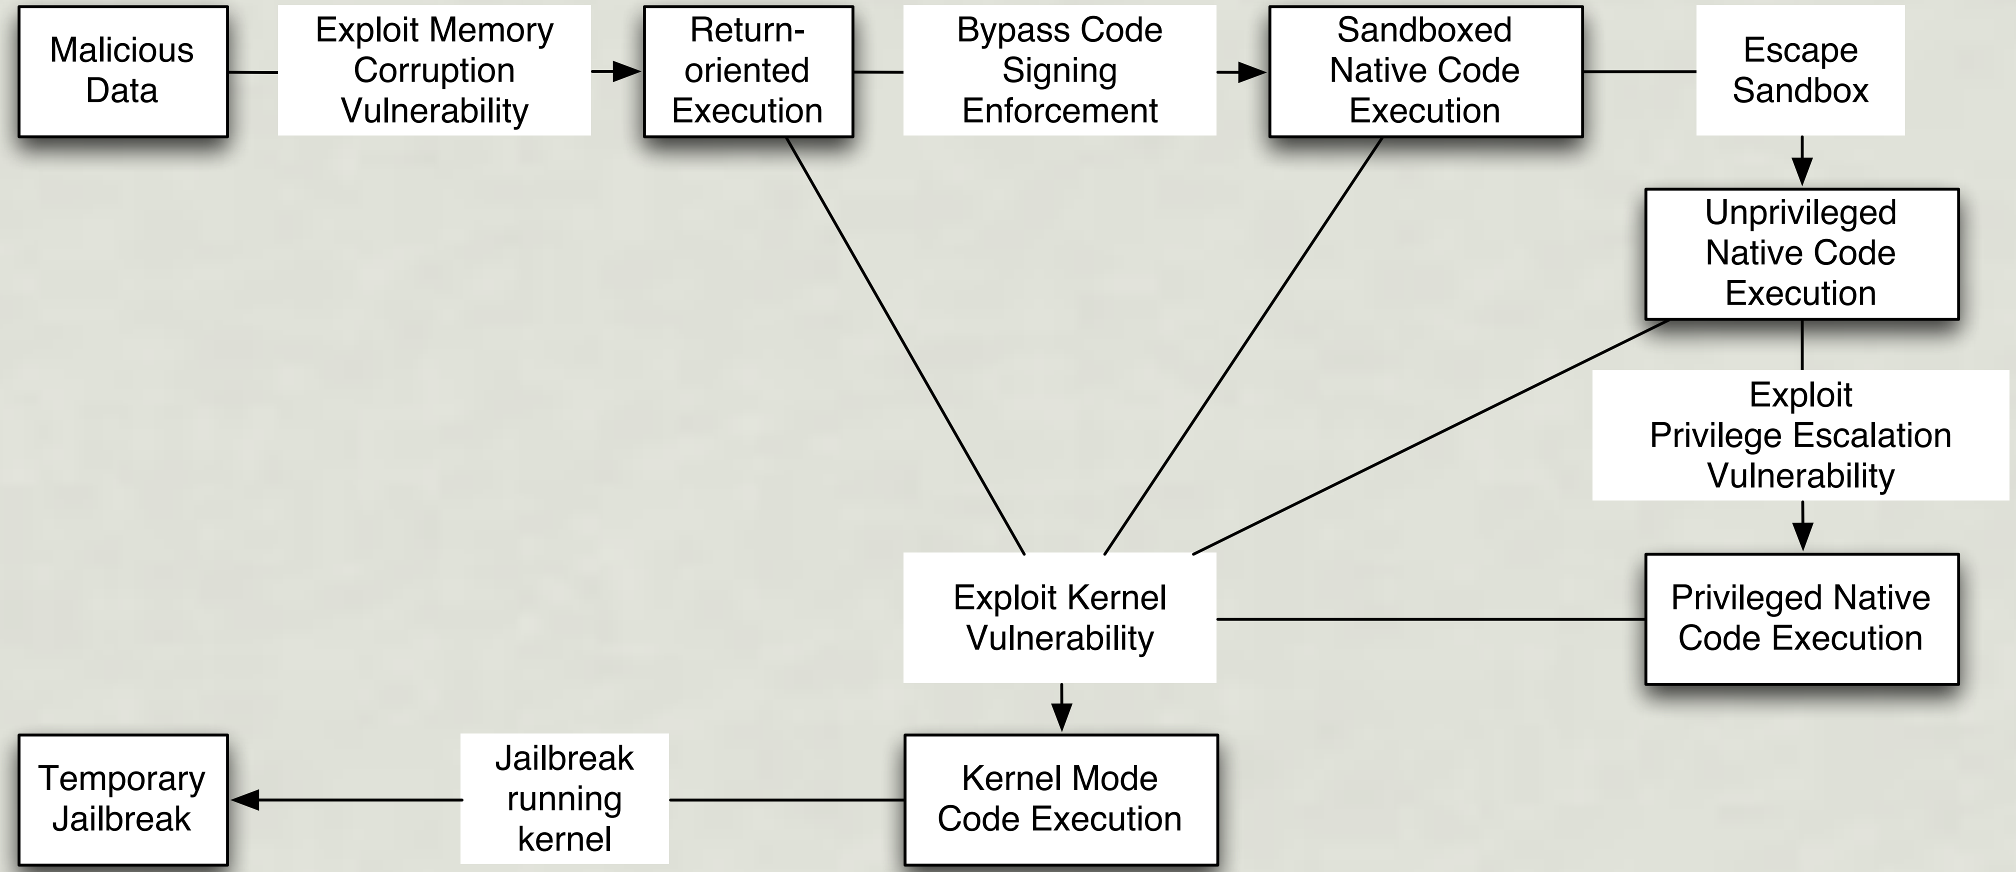
- Introduction
- ASLR
- Code Signing
- Sandboxing
- Data Encryption

Introduction

Security Concerns

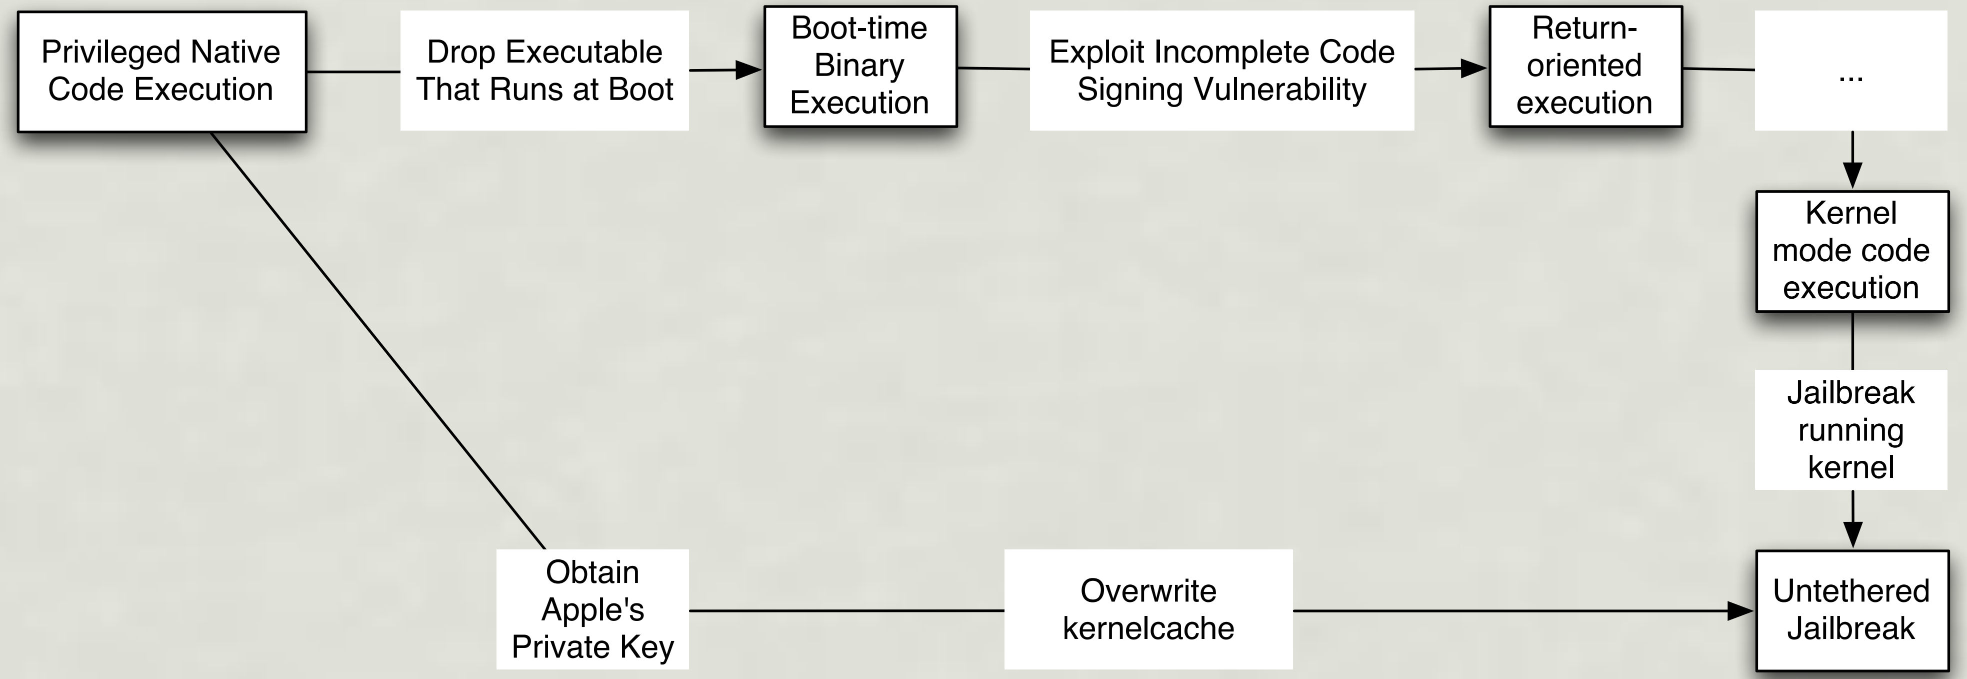
- Sensitive data compromise from lost/stolen device
  - What data can be recovered by attacker?
- Malicious Apps
  - What is the likelihood of DroidDream for iOS?
- Remote attacks through web browser, e-mail, etc.
  - Is that a desktop (aka APT target) in your pocket?

Remote Attack Graph



Malicious Data
Exploit Memory Corruption Vulnerability
Return-oriented Execution
Bypass Code Signing Enforcement
Sandboxed Native Code Execution
Escape Sandbox
Unprivileged Native Code Execution
Exploit Privilege Escalation Vulnerability
Privileged Native Code Execution
Exploit Kernel Vulnerability
Kernel Mode Code Execution
Jailbreak running kernel
Temporary Jailbreak

Persistence Attack Graph



Privileged Native Code Execution
Drop Executable That Runs at Boot
Boot-time Binary Execution
Exploit Incomplete Code Signing Vulnerability
Return-oriented execution
...
Kernel mode code execution
Jailbreak running kernel
Untethered Jailbreak
Obtain Apple's Private Key
Overwrite kernelcache

Address Space Layout Randomization

Security Concerns

- How hard is it to remotely exploit built-in or third-party applications?
  - Malicious web page in Safari or third-party app with embedded browser (i.e Facebook, Twitter)
  - Malicious e-mail message or attachment in Mail
  - Man-in-the-middle and corrupt network communication of third-party apps

iOS 4.3 ASLR

- ASLR is a common runtime security feature on desktop and server operating systems and is a good generic protection against remote exploits
- iOS 4.3 introduced ASLR support
    - iOS 4.3 requires iPhone 3GS and later (ARMv7)
- Apps must be compiled with PIE support for full ASLR, otherwise they only get partial ASLR
    - iOS 4.3 built-in apps and executables are all PIE

ASLR with PIE

Executable	Heap	Stack	Libraries	Linker
0xd2e48	0x1cd76660	0x2fecf2a8	0x35e3edd1	0x2fed0000
0xaae48	0x1ed68950	0x2fea72a8	0x35e3edd1	0x2fea8000
0xbbe48	0x1cd09370	0x2feb82a8	0x35e3edd1	0x2feb9000

Partial vs. Full ASLR

PIE	Main Executable	Heap	Stack	Shared Libraries	Linker
No	Fixed	Randomized per execution	Fixed	Randomized per device boot	Fixed
Yes	Randomized per execution	Randomized per execution (more entropy)	Randomized per execution	Randomized per device boot	Randomized per execution

Identifying PIE support

- otool -hv <executable>

```
    $ otool -hv MobileSafari

    MobileSafari:
    Mach header
          magic cputype cpusubtype  caps    filetype ncmds sizeofcmds      flags
       MH_MAGIC     ARM         V7  0x00     EXECUTE    40       4560   NOUNDEFS DYLDLINK
    TWOLEVEL PIE
```

- hexdump

```
    $ hexdump -C MobileSafari | head
00000000  ce fa ed fe 0c 00 00 00  09 00 00 00 02 00 00 00  |................|

00000010  28 00 00 00 d0 11 00 00  85 00 20 00 01 00 00 00  |(......... .....|
```

PIE in Real-World Apps?

Top 10 Free Apps

App	Version	Post Date	PIE
Songify	1.0.1	June 29, 2011	No
Happy Theme Park	1.0	June 29, 2011	No
Cave Bowling	1.10	June 21, 2011	No
Movie-Quiz Lite	1.3.2	May 31, 2011	No
Spotify	0.4.14	July 6, 2011	No
Make-Up Girls	1.0	July 5, 2011	No
Racing Penguin, Flying Free	1.2	July 6, 2011	No
ICEE Maker	1.01	June 28, 2011	No
Cracked Screen	1.0	June 24, 2011	No
Facebook	3.4.3	June 29, 2011	No

Bottom Line

- All built-in apps in iOS 4.3 have full ASLR with PIE support
- Third-party apps are rarely compiled with PIE support and run with partial ASLR
    - Static location of dyld facilitates exploitation by providing known executable material at a known place (code reuse, return-oriented programming, etc)
    - Applications using a UIWebView are the highest risk (embedded browser in Twitter, Facebook, etc)

Code Signing

Security Concerns

- Can this application be trusted to run on my device?
  - Who (real-world entity) wrote it?
    - How do we know it’s really them?
  - Does it have any hidden functionality?
    - Can it change functionality at run time?

Code Signing

- Mandatory Code Signing
    - Every executable binary or application must have a valid and trusted signature
    - Enforced when an application or binary is executed
- Code Signing Enforcement
    - Processes may only execute code that has been signed with a valid and trusted signature
    - Enforced at runtime

Mandatory Code Signing

- Code Signing security model
  - Certificates
  - Provisioning Profiles
  - Signed Applications
  - Entitlements

Certificates

- Identify the real-world author or publisher of a piece of software
    - i.e. Apple verifies individual/company real-world credentials
- Must be issued by and signed by Apple
- Developers are assigned unique application identifier prefixes

Provisioning Profiles

- The Provisioning Profile itself must be signed by Apple
- Configures an iOS device to trust software signed by the embedded certificate
    - Defines which entitlements the developer is permitted to give to applications they sign
- Profile may be tied to one specific device or global
- Development vs. Distribution provisioning profiles

Distribution Models

- ***On-Device Development*** allows developers to build and test applications on their own devices
- ***Ad-Hoc Distribution*** allows developers to beta test applications on up to 100 other users' devices
- ***AppStore Distribution*** allows developers to publish applications on the iTunes AppStore
- ***In-House Distribution*** allows Enterprise Developers to distribute their custom applications to any device

OTA App Distribution

- Ad-Hoc and In-House Provisioning Profiles can be distributed with the Application in a single archive
- Developer must host the application .ipa archive and manifest plist file on a web server
- Link to manifest can be sent via e-mail, SMS, or other web page
- When user clicks the link, iOS displays developer and application name in a cancel/allow dialog

Code Signing Internals

- AppleMobileFileIntegrity kernel extension responsible for implementing code signing security policy
    - Installs MAC Framework policy hooks to enforce Mandatory Code Signing and Code Signing Enforcement
- Dynamic code signing implemented in xnu virtual memory system (see kernel sources)
    - Process' code signing status tracked in proc.csflags

MAC Hook	API Description	AMFI Usage
mpo_vnode_check_signature	Determine whether the given code signature or code directory SHA1 hash are valid.	Checks for the given CDHash in the trust caches. If it is not found, the full signature is validated by performing an RPC call to the userspace amfid daemon. If a particular global flag is set (amfi_get_out_of_my_way), then any signature is allowed.
mpo_vnode_check_exec	Determine whether the subject identified by the credential can execute the passed vnode.	Sets the code signing CS_HARD and CS_KILL flags, indicating that the process shouldn’t load invalid pages and that the process should be killed if it becomes invalid.
mpo_proc_check_get_task	Determine whether the subject identified by the credential can get the passed process's task control port.	Allows if the target process has the get-task-allow entitlement and the source task has task_for_pid-allow entitlement.

MAC Hook	API Description	AMFI Usage
mpo_proc_check_run_cs_invalid	Determine whether the process may execute even though the system determined that it is untrusted (unidentified or modified code)	Allow execution if the process has the get-task-allow, run-invalid-allow, or run-unsigned-code entitlements or an RPC call to amfid returns indicating that unrestricted debugging should be allowed.
mpo_proc_check_map_anon	Determine whether the subject identified by the credential should be allowed to obtain anonymous memory with the specified flags and protections.	Allows the process to allocate anonymous memory if and only if the process has the dynamic-codesigning entitlement.

Normal Code Signature

```
Executable=/.../9D3A8D85-7EDE-417A-9221-1482D60A40B7/iBooks.app/iBooks
Identifier=com.apple.iBooks
Format=bundle with Mach-O universal (armv6 armv7)
CodeDirectory v=20100 size=14585 flags=0x0(none) hashes=721+5 location=embedded
Hash type=sha1 size=20
CDHash=ac93a95bd6594f04c209fb6bf317d148b99ac4d7
Signature size=3582
Authority=Apple iPhone OS Application Signing
Authority=Apple iPhone Certification Authority
Authority=Apple Root CA
Signed Time=Jun 7, 2011 11:30:58 AM
Info.plist entries=36
Sealed Resources rules=13 files=753
Internal requirements count=2 size=344
```

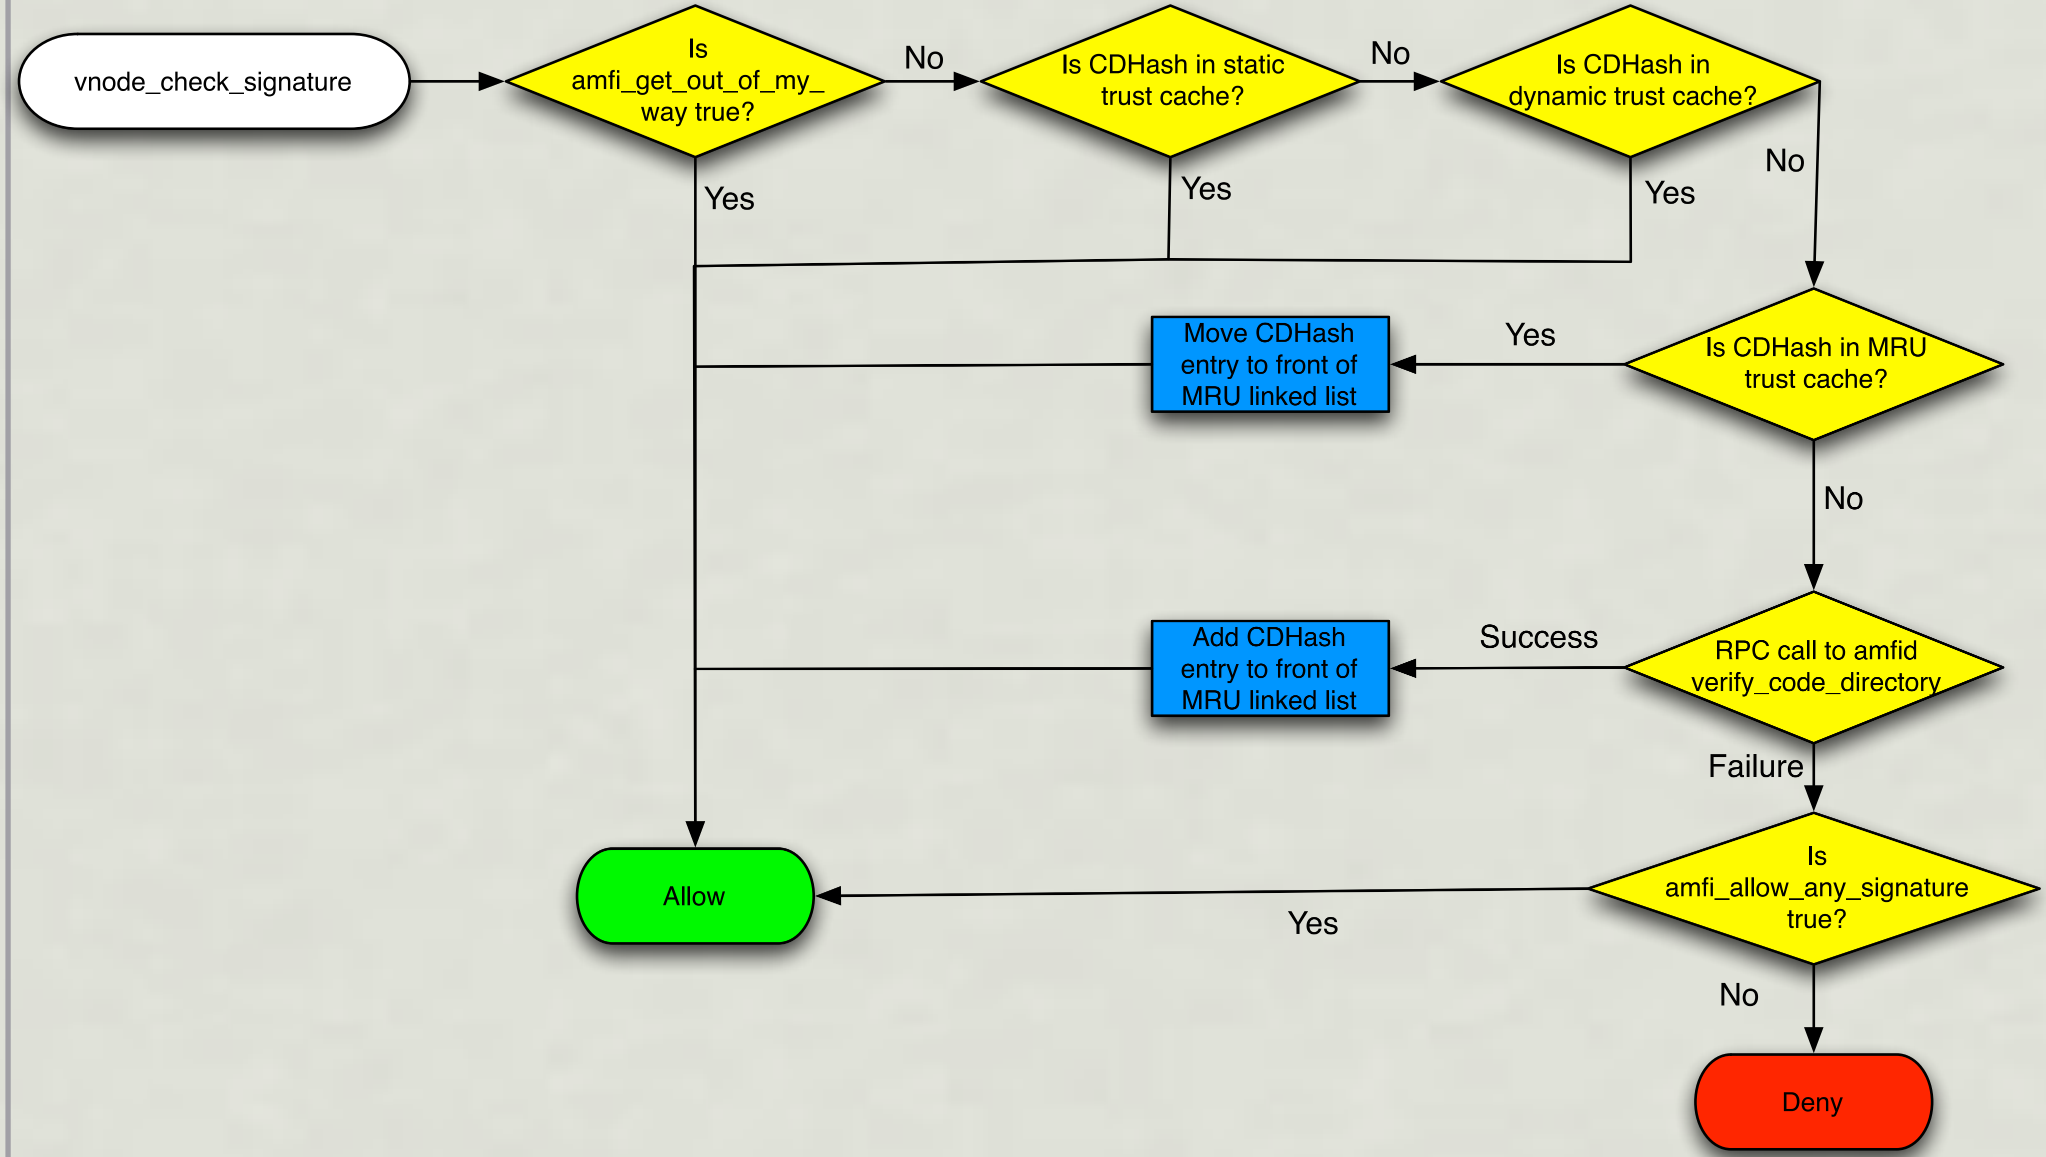
Ad-Hoc Code Signature

```
Executable=/Developer/usr/bin/debugserver
Identifier=com.apple.debugserver
Format=Mach-O universal (armv6 armv7)
CodeDirectory v=20100 size=1070 flags=0x2(adhoc) hashes=45+5 location=embedded
CDHash=6a2a1549829f4bff9797a69a1e483951721ebcbd
Signature=adhoc
Info.plist=not bound
Sealed Resources=none
Internal requirements count=1 size=152
```

Code Signature Verification

- iOS kernel has a *static trust cache* of CDHashes
- AMFI IOKit UserClient lets root load trust caches into *dynamic trust cache*
    - Trust cache must stored in a signed IMG3
- Kernel performs RPC call to usermode daemon to perform full binary code signature verification
- Kernel stores the CDHash of each verified binary in the *MRU trust cache* linked list

Code Signing Verification



vnode_check_signature
Is amfi_get_out_of_my_way true?
No
Is CDHash in static trust cache?
No
Is CDHash in dynamic trust cache?
Yes
Yes
Yes
No
Move CDHash entry to front of MRU linked list
Yes
Is CDHash in MRU trust cache?
No
Add CDHash entry to front of MRU linked list
Success
RPC call to amfid verify_code_directory
Failure
Allow
Is amfi_allow_any_signature true?
Yes
No
Deny

AMFI Daemon

- /usr/libexec/amfid

Message ID	Subroutine	Description
1000	verify_code_directory	Verifies the given code directory hash and signature for the executable at the given path. This checks whether the signature is valid and that it should be trusted based on the built-in Apple certificates and installed provisioning profiles (if any).
1001	permit_unrestricted_debugging	Enumerates the installed provisioning profiles and checks for a special Apple-internal provisioning profile with the UDID of the current device that enables unrestricted debugging on it.

Bypassing Code Signing

- Incomplete Code Signing[1] Exploits
    - Manipulate dynamic linker to perform stack pivot and execute return-oriented payload
    - Interposition exploit (4.0), Initializers exploit (4.1)
    - More recent exploits use relocations to dynamically adjust ROP payloads to compensate for ASLR
    - iOS 4.3.4 strengthens iOS defenses against these

[1] http://theiphonewiki.com/wiki/index.php?title=Incomplete_Codesign_Exploit

Code Signing Enforcement

- Ensure that process stays dynamically valid
  - No introduction of new executable code
  - Already loaded executable code can’t be changed
- Guarantees that the app code that was reviewed is what runs on the device
  - Also just happens to prevent injecting shellcode

csops

```
int csops(pid_t pid, uint32_t ops, user_addr_t useraddr, user_size_t usersize);
```

- System call to interact with a process' code signing state
  - Get code signing status
  - Set code signing flags (CS_HARD, CS_KILL)
  - Get executable pathname, code directory hash, active running slice

CS Ops

Flag	Value	Description
CS_OPS_STATUS	0	Return process CS status
CS_OPS_MARKINVALID	1	Invalidate process
CS_OPS_MARKHARD	3	Set CS_HARD flag
CS_OPS_MARKKILL	4	Set CS_KILL flag
CS_OPS_PIDPATH	5	Get executable’s pathname
CS_OPS_CDHASH	6	Get code directory hash
CS_OPS_PIDOFFSET	7	Get offset of active Mach-O slice

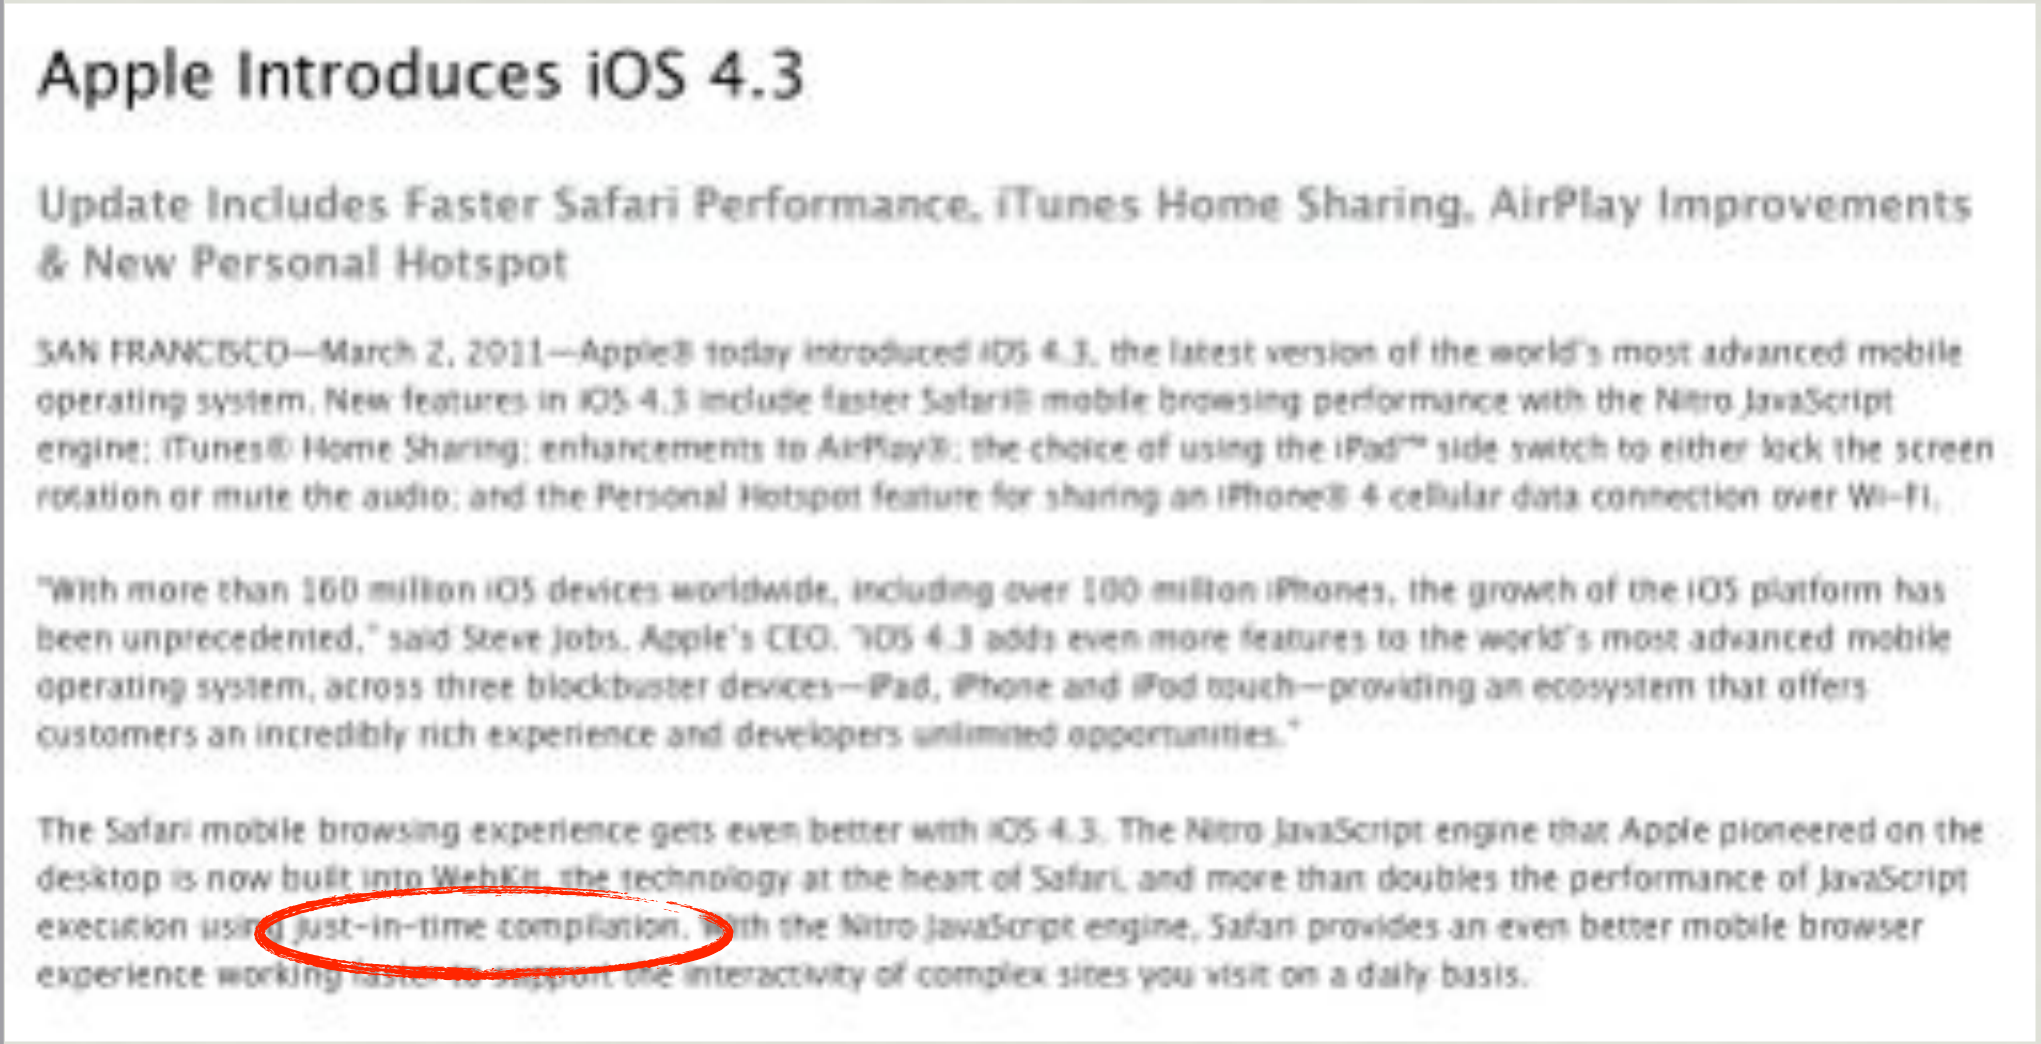
CS Status Flags

Flag	Value	Description
CS_VALID	0x00001	Process is dynamically valid
CS_HARD	0x00100	Process shouldn’t load invalid pages
CS_KILL	0x00200	Process should be killed if it becomes dynamically invalid
CS_EXEC_SET_HARD	0x01000	Process should set CS_HARD on any exec’d child
CS_EXEC_SET_KILL	0x02000	Process should set CS_KILL on any exec’d child
CS_KILLED	0x10000	The process was killed by the kernel for being dynamically invalid

CS_HARD and CS_KILL

- CS_HARD
  - Enforce W^X (Writable XOR Executable) memory page policy
  - Do not allow invalid memory pages to be loaded
  - `mprotect(addr, len, ... | PROT_EXEC) => EPERM`
- CS_KILL
  - Kill the process if it becomes dynamically invalid
  - `mprotect(text, len, PROT_READ | PROT_WRITE)`
    ... Modify code page ...
    `mprotect(text, len, PROT_READ | PROT_EXEC) => SIGKILL`

iOS 4.3 Adds JavaScript JIT



Apple Introduces iOS 4.3

Update Includes Faster Safari Performance, iTunes Home Sharing, AirPlay Improvements & New Personal Hotspot

SAN FRANCISCO—March 2, 2011—Apple® today introduced iOS 4.3, the latest version of the world's most advanced mobile operating system. New features in iOS 4.3 include faster Safari® mobile browsing performance with the Nitro JavaScript engine; iTunes® Home Sharing; enhancements to AirPlay®; the choice of using the iPad™ side switch to either lock the screen rotation or mute the audio; and the Personal Hotspot feature for sharing an iPhone® 4 cellular data connection over Wi-Fi.

"With more than 160 million iOS devices worldwide, including over 100 million iPhones, the growth of the iOS platform has been unprecedented," said Steve Jobs, Apple's CEO. "iOS 4.3 adds even more features to the world's most advanced mobile operating system, across three blockbuster devices—iPad, iPhone and iPod touch—providing an ecosystem that offers customers an incredibly rich experience and developers unlimited opportunities."

The Safari mobile browsing experience gets even better with iOS 4.3. The Nitro JavaScript engine that Apple pioneered on the desktop is now built into WebKit, the technology at the heart of Safari, and more than doubles the performance of JavaScript execution using just-in-time compilation. With the Nitro JavaScript engine, Safari provides an even better mobile browser experience working faster to support the interactivity of complex sites you visit on a daily basis.

```
# ldid -e /Applications/MobileSafari.app/MobileSafari
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE plist PUBLIC "-//Apple//DTD PLIST 1.0//EN" "http://www.apple.com/DTDs/
PropertyList-1.0.dtd">
<plist version="1.0">
<dict>
     <key>com.apple.coreaudio.allow-amr-decode</key>
     <true/>
     <key>com.apple.coremedia.allow-protected-content-playback</key>
     <true/>
     <key>com.apple.managedconfiguration.profiled-access</key>
     <true/>
     <key>com.apple.springboard.opensensitiveurl</key>

     </array>
     <key>platform-application</key>
     <true/>
     <key>seatbelt-profiles</key>
     <array>
          <string>MobileSafari</string>
     </array>
</dict>
</plist>
```

AMFI MAC Hook

MAC Hook	API Description	AMFI Usage
mpo_proc_check_map_anon	Determine whether the subject identified by the credential should be allowed to obtain anonymous memory with the specified flags and protections.	Allows the process to allocate anonymous memory if and only if the process has the dynamic-codesigning entitlement.

Dynamic Code Signing

- The **dynamic-codesigning** entitlement allows the process to map anonymous memory *with any specified protections*.
- Only MobileSafari has this entitlement in iOS 4.3
  - Necessary for JavaScript native JIT (“Nitro”)
  - Previously MobileSafari did bytecode JIT

Bottom Line

- Mandatory Code Signing in iOS is strong defense against execution of unauthorized binaries
    - Requires incomplete code signing exploits to bypass and obtain return-oriented execution
- Code signing forces attackers to develop fully ROP payloads
    - DEP/NX only require a ROP stage to allocate new executable memory and copy shellcode into it
- JIT support in Safari reduces ROP requirements to a stage

Sandboxing

Security Concerns

- Can an exploited app or malicious third-party app...
  - Access or modify data belonging to other applications?
  - Access or modify potentially sensitive user information?
  - Break out of the sandbox and rootkit iOS?

Sandboxing in iOS

- Based on same core technologies as Mac OS X sandbox
  - See Dion's "The Apple Sandbox" from BHDC 2011 for more information on internals
  - Modified his tools to decompile iOS 4.3 profiles
- iOS only supports static built-in profiles
- Process' sandbox profile is determined by seatbelt-profiles entitlement

Sandbox Kernel Extension

- Installs MAC Hooks on all secured operations
- MAC hooks evaluate a binary decision tree to make access determination
- Sandbox profiles consist of the set of decision trees defined for each defined operation with conditional filters based on requested resource
    - i.e. does file name match this regex?

Built-in Sandbox Profiles

- Background daemons: accessoryd, apsd, dataaccessd, iapd, mDNSResponder, etc.
- Built-in Apps: MobileMail, MobileSafari, MobileSMS, Stocks, YouTube, etc.
- Third-party Apps: container and container2 (iBooks)

Third-Party Applications

- Assigned a dedicated portion of the file system ("container" or "application home directory") each time it is installed
- Can a rogue application escape the sandbox and read other applications' data or modify the device firmware?

App Home Directory

Subdirectory	Description
<AppName>.app/	The signed bundle containing the application code and static data
Documents/	App-specific user-created data files that may be shared with the user's desktop through iTunes's "File Sharing" features
Library/	Application support files
Library/Preferences/	Application-specific preference files
Library/Caches/	App-specific data that should persist across successive launches of the application but not needed to be backed up
tmp/	Temporary files that do not need to persist across successive launches of the application

Container Profile

- See whitepaper for detailed description and tarball for fully decompiled profile
- Summary:
  - File access is generally restricted to app’s home directory
  - Can read media: songs, photos, videos
  - Can read and write AddressBook
  - Some IOKit User Clients are allowed
  - All Mach bootstrap servers are allowed

Mach Bootstrap Servers

- All Mach tasks have access to a bootstrap port to lookup service ports for Mach RPC services
    - On iOS, this is handled by launchd
- 141 RPC servers accessible from apps
    - Risk of being exploited over RPC
    - May present risk of allowing apps to perform unauthorized or undesirable actions

Example Servers

- com.apple.UIKit.pasteboardd
- com.apple.springboard
- com.apple.MobileFileIntegrity
- com.apple.fairplayd
- com.apple.mobile.obliteration
- com.apple.iTunesStore.daemon

Bottom Line

- Remote exploits are most likely able to break out of sandbox by exploiting iOS kernel or IOKit UserClients permitted by sandbox profile
- Rogue applications would need to exploit and jailbreak the kernel to escape sandbox
  - Could repurpose kernel exploits from Jailbreaks
  - Apple’s review will likely catch this
  - OTA app distribution bypasses Apple’s review (target user interaction required)

Data Encryption

Security Concerns

- What sensitive data may be compromised if a device is lost or stolen?
  - What data is encrypted?
  - What data is protected by the passcode?
- How hard is it to crack iOS passcodes?
  - Can they be cracked off the device?

Data Encryption

- What you need to know about Data Encryption in iOS to make informed deployment and configuration decisions
- For more internals and implementation details, refer to excellent “iPhone Data Protection in Depth”[1] from HITB Amsterdam 2011

[1] http://esec-lab.sogeti.com/dotclear/public/publications/11-hitbamsterdam-iphonedataprotection.pdf

Encryption Layers

- Entire filesystem is encrypted using block-based encryption with **File System Key**
  - FSK is stored on the flash, encrypted using key derived from UID Key
- Each file has a unique encryption key stored in an extended attribute, protected by **Class Key**
  - Class Keys are stored in the System KeyBag
- Some Class Keys are protected by a key derived from the user’s passcode (**Passcode Key**)
- Certain Class Keys are also protected by the device-specific **UID Key** that is embedded in hardware and inaccessible to code running on CPU

Data Protection API

- Applications must specifically mark files on the filesystem and Keychain items with a Protection Class in order for them receive greater protection
    - Files and Keychain items can be made inaccessible when the device is locked (protected by Passcode Key)
    - Keychain items can be made non-migratable to other devices (protected by UID Key)

Data Protection Coverage

- In iOS 4, DP is only used by the built-in Mail app
  - Protects all mail messages, attachments, and indexes
  - Protects passwords for IMAP, SMTP servers
  - Protected items are only accessible when device is unlocked
  - Exchange ActiveSync passwords are accessible always to preserve remote wipe functionality
- DP is also used for automatic UI screenshots generated when user hits the Home Button.

Attacking Passcode

- With knowledge of passcode, you can decrypt the data protected by iOS Data Protection
- Increasing incorrect passcode delay and forced device wipe after too many incorrect guesses are enforced by UI
  - Springboard -> MobileKeyBag Framework -> AppleKeyStore IOKit UserClient -> AppleKeyStore Kernel Extension
- On a jailbroken device, you can guess passcodes directly using the MKB Framework or AppleKeyStore IOKit User Client
  - Jailbreak device using BootROM exploit, install SSH bundle, restart, and log in via SSH over USBMUX

Passcode Key

- Passcode Key is derived using PBKDF2 using AES with the Device Key as the hashing function
  - Cannot derive key off of the device that created it unless you can extract the UID Key from the hardware
  - Iteration count of PBKDF2 is tuned to hardware speed
  - Roughly 9.18 guesses/second on iPhone4

Worst-Case Passcode Guessing Time (iPhone4)

Passcode Length	Complexity	Time
4	Numeric	18 minutes
4	Alphanumeric	51 hours
6	Alphanumeric	8 years
8	Alphanumeric	13 thousand years
8	Alphanumeric, Complex	2 million years

Assuming 26 lowercase letters + 10 digits + 34 complex characters = 70 chars

Bottom Line

- 6-character alphanumeric passcodes are probably sufficient
  - Unless attacker can extract UID Key from hardware
- Lack of thorough Data Protection coverage is a serious issue
  - Wait to see what iOS 5 covers
  - Audit third-party apps for Data Protection usage
- iPad2 and later have no public Boot ROM exploits, making attacks on lost devices much more difficult and unlikely

Conclusion

Findings

- Third-party applications without PIE support won't get full ASLR and are easier to exploit, especially if they have an embedded web browser
- In-House Distribution Certificates and Provisioning Profiles allow their apps to run on all devices, Enterprise Developers should protect them
    - Attackers could steal them and use OTA distribution and social engineering to bypass Apple's AppStore review
- As of iOS 4.3, Safari's dynamic-codesigning entitlement makes browser exploits require a ROP stage, not full ROP
- All 140+ iOS Mach RPC servers are allowed through sandbox profile, may allow apps to perform undesirable actions

Findings

- Although filesystem is encrypted with block-level encryption, exploiting the device’s BootROM and booting jailbroken can be used to read the data
- In iOS 4, Data Protection only protects Mail messages and passwords (and screenshots) with user’s passcode
- While passcode must be cracked on-device, default simple passcodes are brute-force cracked in less than 20 minutes

iOS vs. Android/BlackBerry

- How does iOS security compare to Android and BlackBerry?
  - iOS Data Protection not nearly as thorough as BlackBerry’s Content Protection
  - BlackBerry’s browser is based on same WebKit as iOS and Android browsers, but has no sandbox (see PWN2OWN 2011)
  - Android has no ASLR or NX, significantly weaker app isolation, and root can load kernel modules

Unique to iOS

- Dynamic Code Signing Enforcement
  - Stronger defense against remote native code injection than DEP/NX/W^X
- Kernel is secured against user mode code
  - Even the superuser (root) has to exploit the kernel in order to run kernel mode code

On Jailbreaking

- Modern jailbreaks require multiple exploits to defeat the layered protections in iOS
  - 1 BootROM exploit required for tethered jailbreak
  - 1 BootROM, 1 Incomplete Code Signing, and 1 Kernel exploit required for untethered jailbreak
  - 1 Safari, 1 Kernel exploit required for remote temporary jailbreak
  - 1 Safari, 1 Kernel, 1 Incomplete Code Signing exploit for remote untethered jailbreak (i.e. JailbreakMe)
- Jailbreaking essentially reduces iOS security to level of Android

Attacks You Should Care Most About

- Lost/stolen device
  - How well is iOS and third-party app data protected?
- Repurposed jailbreak exploits
  - JailbreakMe PDF attacks via e-mail or web
- Stolen Enterprise In-House Distribution Certificate and social engineering OTA app links
  - Apps containing kernel exploit from JB

Hardware Advice

- iPhone 3G and earlier shouldn’t be allowed
  - No longer supported by iOS
  - No device encryption support
  - Permanently jailbroken via Boot ROM exploits
- iPad 2 has no public Boot ROM exploits, making it safer than earlier iOS devices

Bottom Line

- Should you deploy iOS devices for enterprise use?
  - Wait for iOS 5, hopefully DP API is more thorough
  - Audit any apps w/ enterprise data for Data Protection API usage or poor use of custom cryptography
  - Prefer iPad2 and to-be-released iPhone because they don’t have known BootROM exploits
  - Use an MDM product and apply security policy to all devices
  - Don’t let users jailbreak the devices or else you may as well just give them Android devices

iOS Fuzz Farm

iOS Fuzz Farm

- 4 x Apple TVs, switch, power strip = ~$500
  - Totally headless, only accessible via SSH
  - Perfect size for operating out of small NYC apartments
- Nowhere near operational yet
  - Need to write iOS test harness
  - Some mechanism for testing GUI iOS apps

Questions?
